

Optimization algorithms for long-term operation of energy hubs

Marta Zagorowska
TU Delft

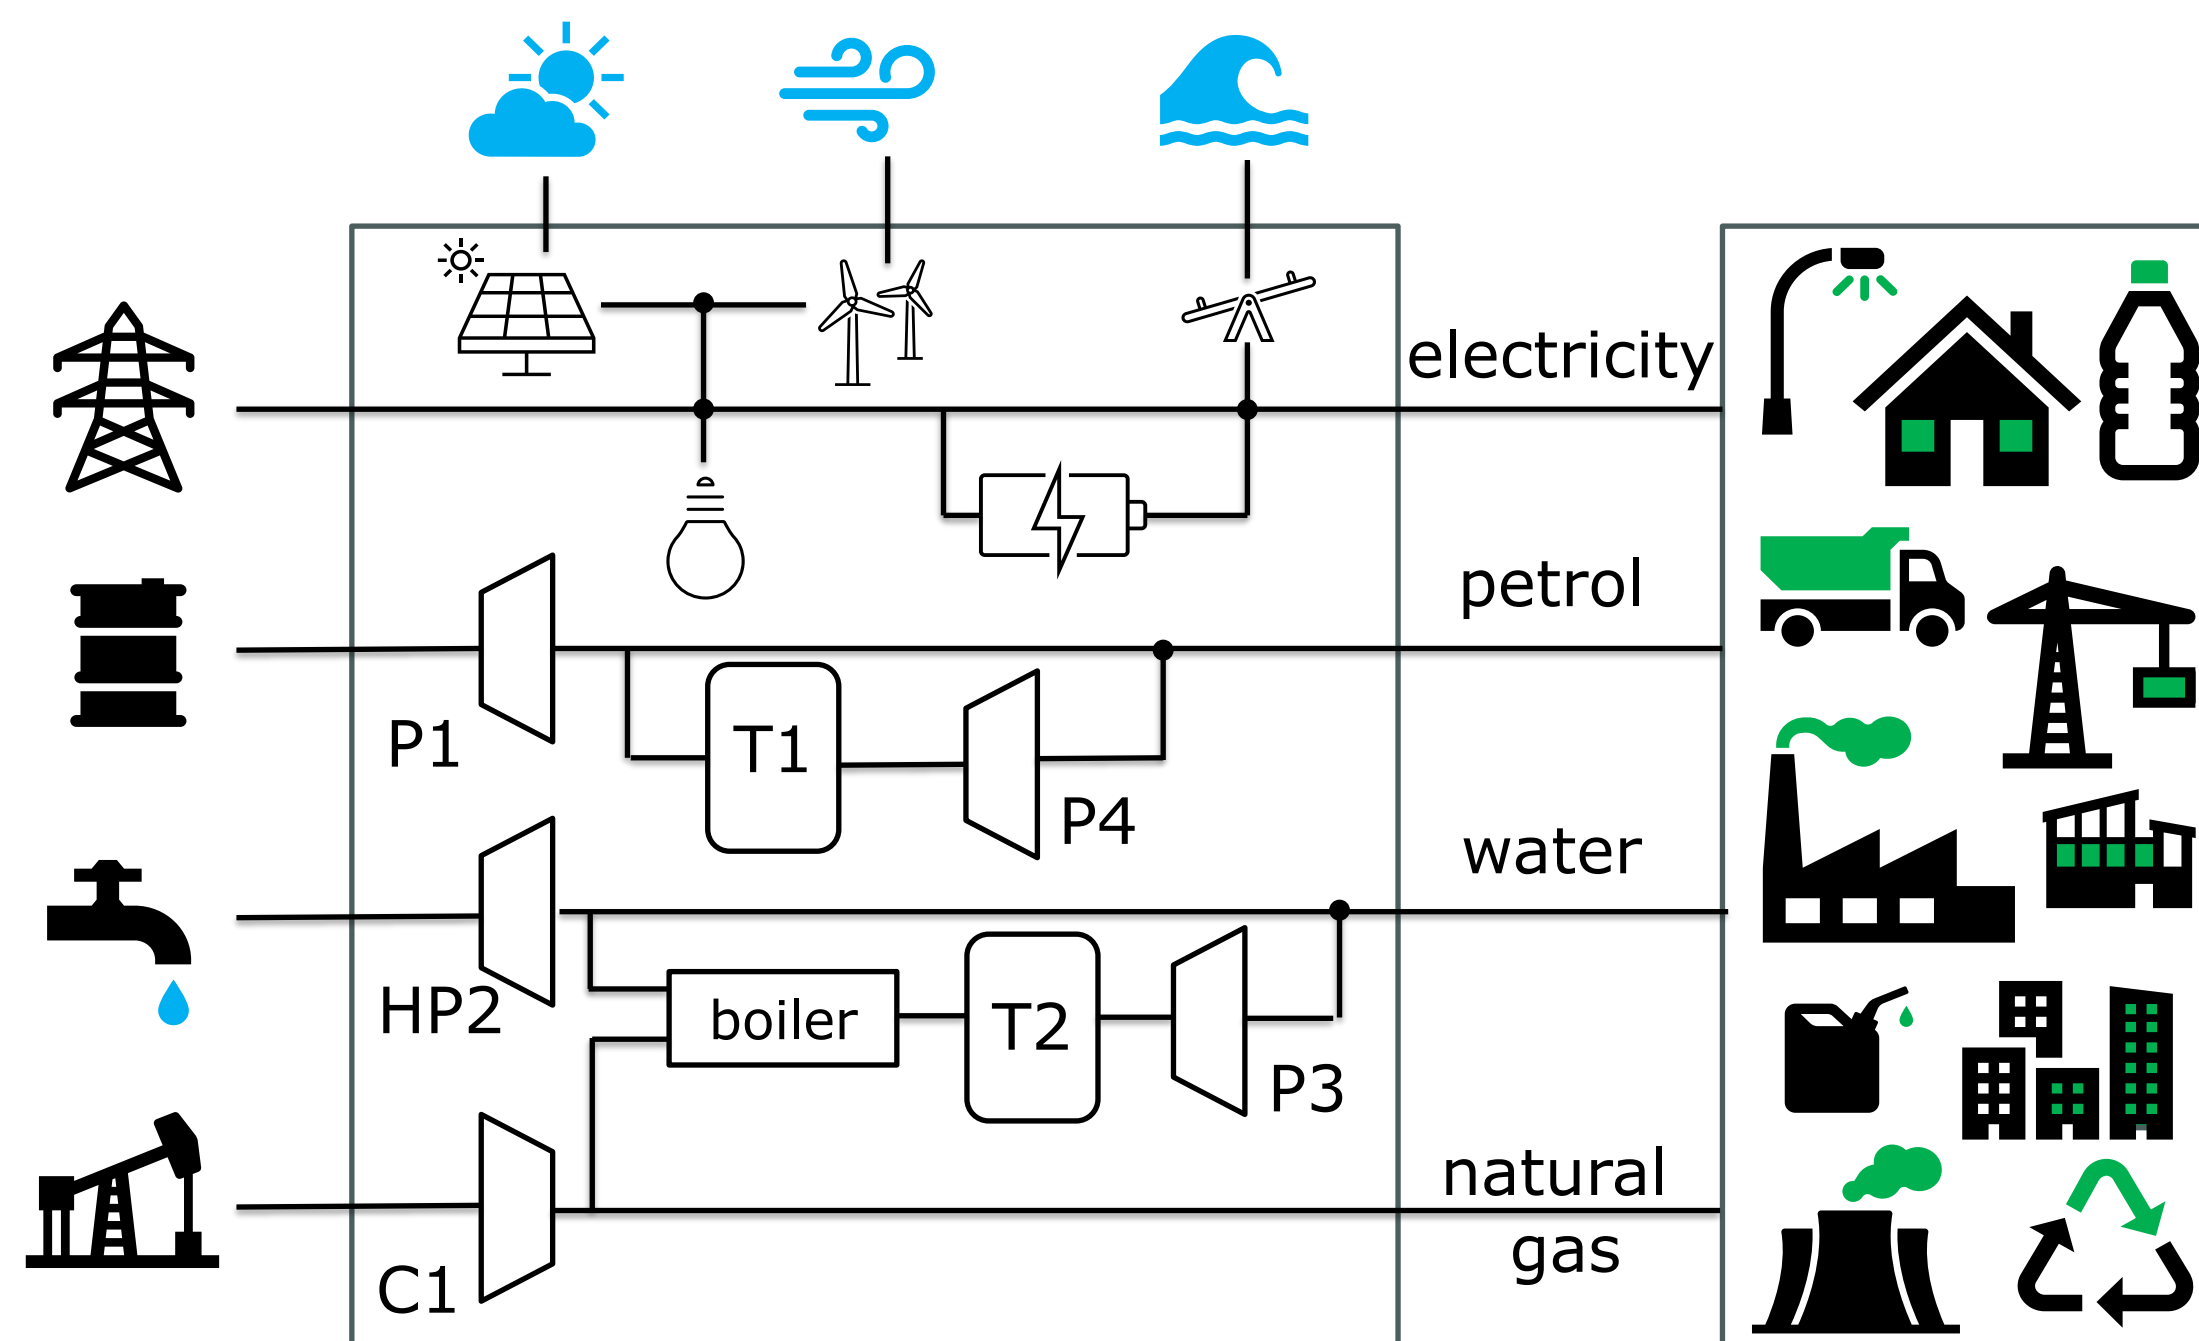

Fig. 1. Energy hub – processing energy carriers to satisfy demand

Challenges:

- **Energy intensive** operation
- Strict **safety requirements**
- **Limited information** available

Idea: use an **optimization** algorithm as a **controller** to reach the **optimum** and **satisfy constraints**

Objective: Minimise power consumption in a compressor station

$$\sum_{i=1}^K W_i (m_i, \eta(m_i, \Delta_i))$$

while satisfying the demand

$$\sum_{i=1}^K m_i = M$$

and staying in the operating range

$$m_i^{\min} \leq m_i \leq m_i^{\max}$$

Inlet flow & pressure

Mass flow through Compressor 1

Mass flow through Compressor 2

Outlet flow & pressure

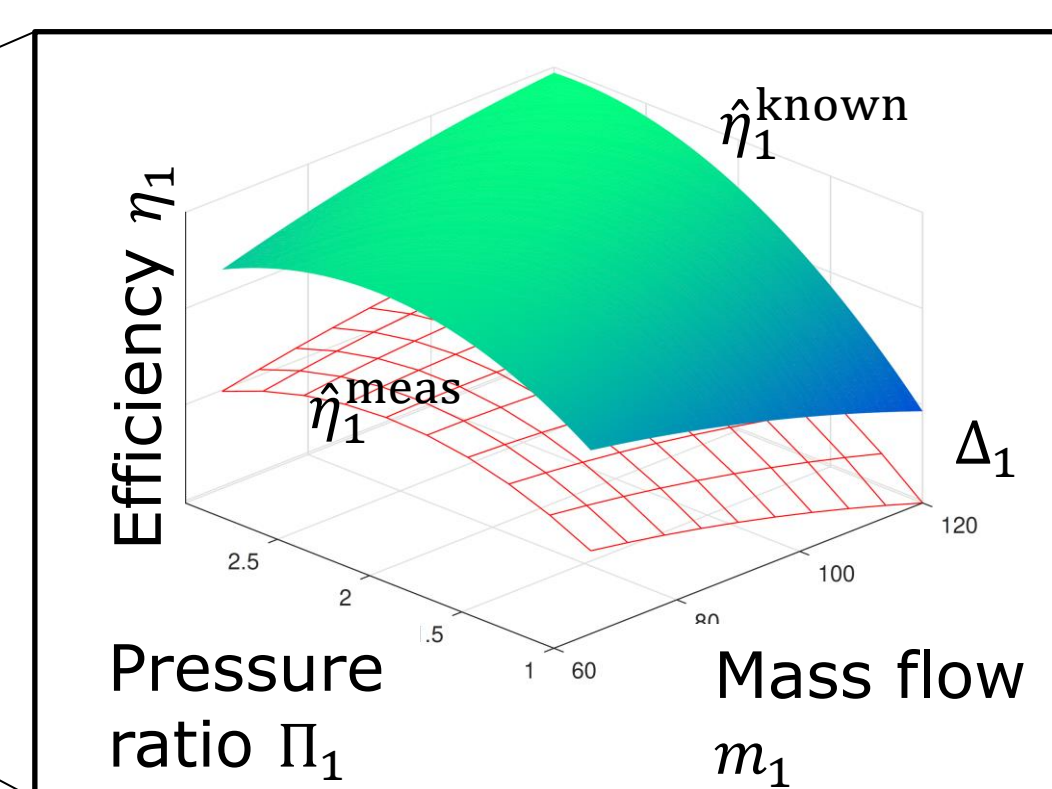

Fig. 2. Compressor station with model mismatch Δ_i

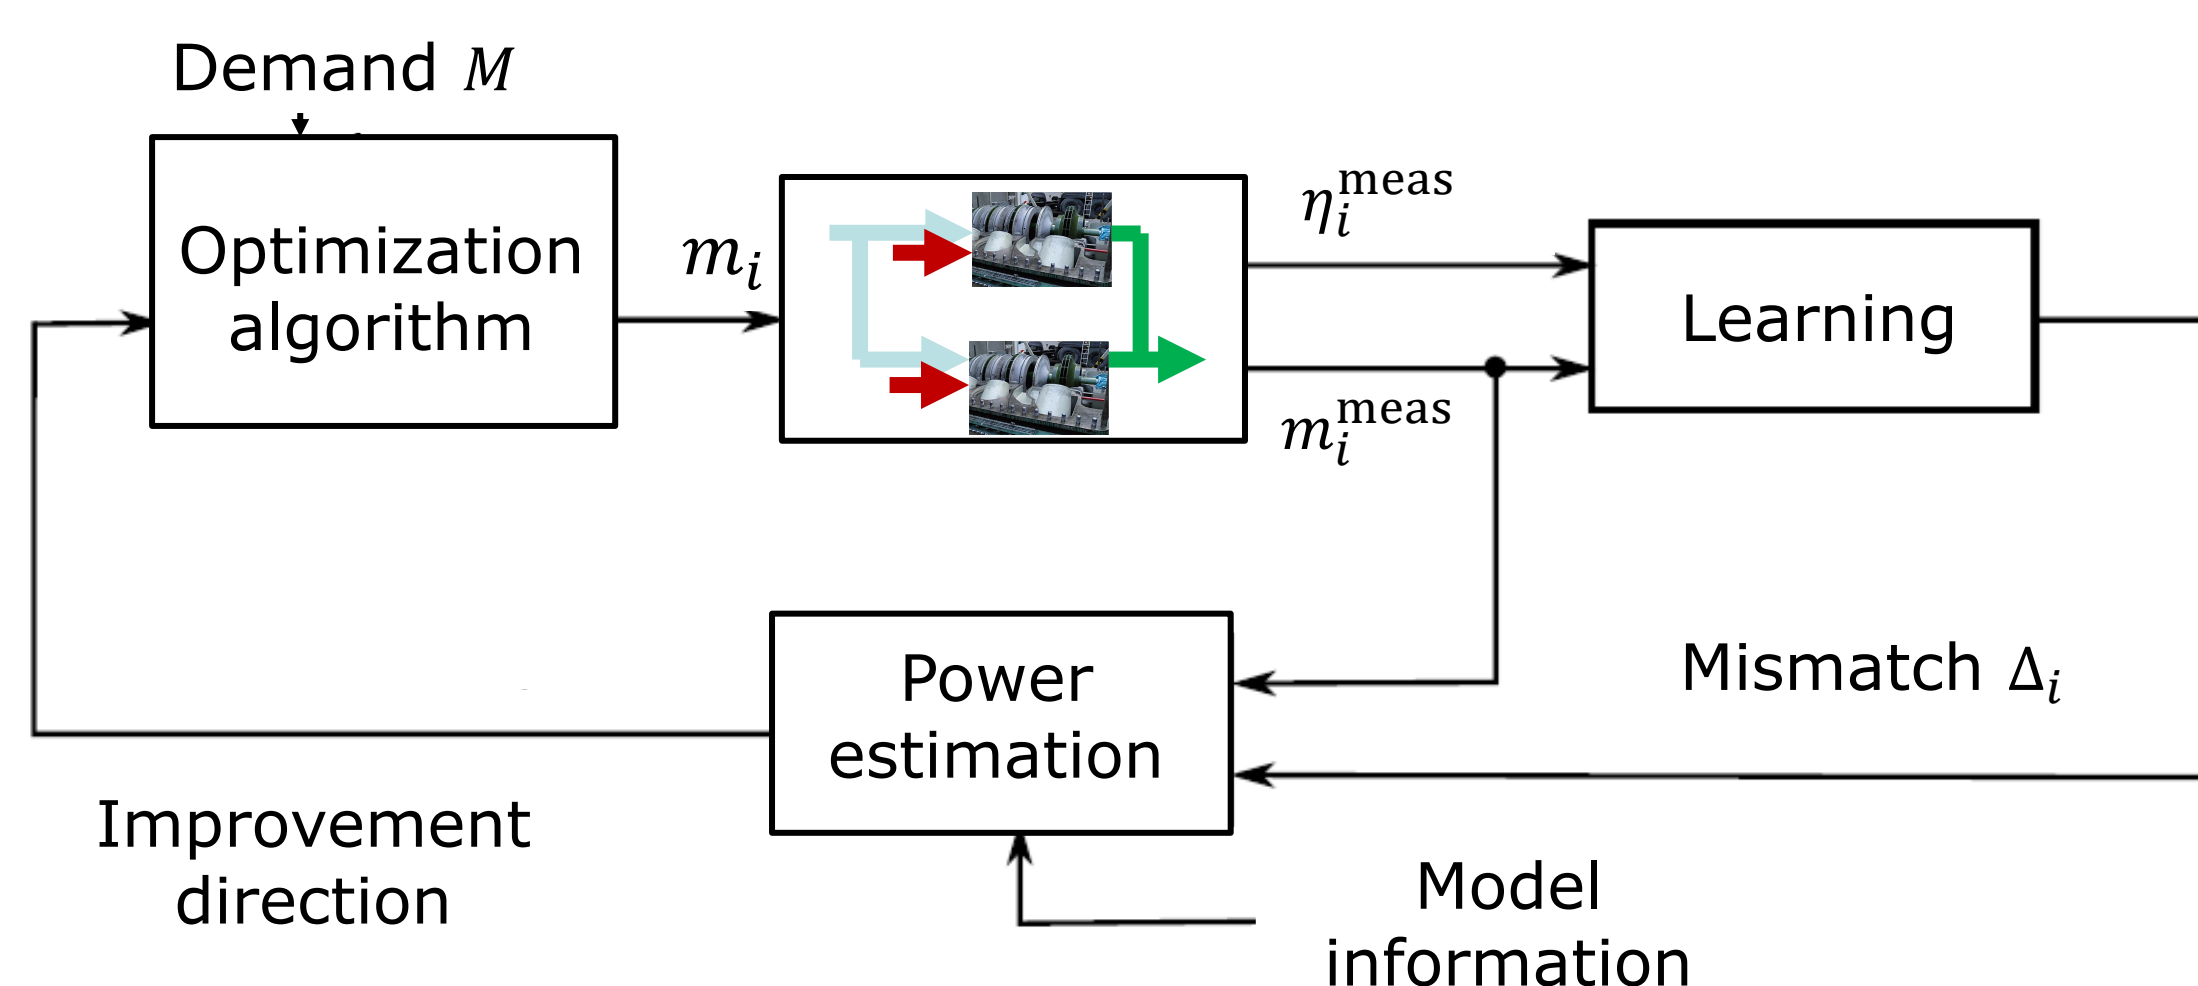

Fig. 3. OFO with learning for systems with model mismatch

Results:
Reduction of power consumption up to **0.8%**

Fig. 4. Power consumption

Outcomes:

- **Optimization** algorithms can be used as **controllers**
- Combining **optimization** and **learning** overcomes model **mismatch**

Open questions:

- How to **implement** such controllers **in practice**?

Ongoing work

Adaptive tuning for long-term operation
